2016

MICHIGAN CORN PERFORMANCE TRIALS

M. Singh, K. Thelen, W. D. Widdicombe and L. A. Williams
Department of Plant, Soil, and Microbial Sciences
Michigan State University

Introduction

The Michigan State University Department of Plant, Soil and Microbial Sciences conduct hybrid corn trials each year in cooperation with Michigan State University AgBio Research stations, seed corn companies, and farmers to determine yield and quality performance.

Entries

Seed companies are invited to enter hybrids in the trials; a fee is charged to cover expenses incurred while conducting the trials. Separate indexes for grain and silage provide a list of all hybrids entered in the 2016 trials (pg. 26 and 31, respectively). Thirteen grain and eleven silage locations were planted. A total of 369 hybrids from 34 brand names make up the 564 entries; that translates into 6,768 separate county plots planted. Company names used in association with hybrid numbers refer to the brand. The hybrid numbers are the companies' designations.

Hybrids that have a seed-applied insecticide that may enhance yield are listed in the table column TRT (Treatment). The "TRAIT" column uses code numbers, listing the hybrid traits provided by the company. Treatment and Trait codes are listed in the tables on page 19.

How to Use This Bulletin

Tables list hybrids alphabetically and contain yield results for each location, plus zone averages. Complete one and two-year yield results are listed in tables for each zone where data is available. One-year single-site results are less reliable than multiple year and multiple location averages, and should be interpreted with more caution. Confidence in corn performance data increases as the number of years and the number of testing locations increase. Results for corn grain and corn silage trials are also listed on our Web site:

<http://www.varietytrials.msu.edu>

To obtain additional published copies of this bulletin please contact the Michigan State University Extension Bulletin Office at the following:

The results shown are the average of four replications grown in close proximity to one another. Two or more plots of the same hybrid in the same field may produce somewhat different results because of uncontrolled variability in the soil and other environmental factors. Replication and randomization of the entries were two methods employed to reduce this variation.

Because these methods do not eliminate all variables, the magnitude of difference necessary for statistical significance has been calculated for yield, moisture content, and test weight. The value calculated as the least significant difference (LSD) is the amount an individual hybrid would have to differ from another hybrid in the same test to be considered significantly different from that hybrid. The coefficient of variability, (CV) is indicative of a trials precision. Trials with low levels of error variation have lower CV values.

The highest yielding hybrid in each trial is indicated with a double asterisk (**) in each table, hybrids that are not significantly different from the highest yielding hybrid are indicated with an asterisk (*). Other agronomic information relative to each trial is given in tables B and C (pg. 25 and 30). Fertilizer amounts are shown as total pounds per acre of nitrogen, P₂O₅, and K₂O applied during the season.

Season in Summary: 2016

Entry forms for participating companies were due March 15th; by the end of March we began receiving the hybrids that made up our trials. After a lot of paper work, printing of labels and placing labels on packets, our students began counting the seeds and filling the packets. The counting process was made easier with an Agriculex ESC-1 seed counter. Packets were sorted by trial and location and placed in a computer generated random planting order. Some of our seed comes from winter production in South America. We are usually receiving seed up to the morning we leave the Agronomy Farm for the first day of planting.

Planting Commenced in Huron County on May 5th and ended in Alger County on May 31st. We experienced several rain delays between May 5th and May 17th. Beginning May 18th, we were able to plant nearly every day until completion. We did, however, have to make an unusual return trip to the Upper Peninsula due to a rain delay at our Alger County location. The planting depth is checked at each individual field and is adjusted according to the tillage practices and soil texture.

Weed control was applied at all fields. All but one weed control application was performed by our cooperators. Fertilizer applications were consistent with rates that were necessary based on soil type, soil samples and cooperator recommendations for their field.

Normally, stand counts are one of the least challenging tasks of the season; this year, stand counts were the most difficult challenge. Finding workers to help complete stand counts was the over-riding issue which slowed the pace in which the fields were counted and thinned.

2016

GROWING SEASON WEATHER SUMMARY

Jeff Andresen, Extension Agricultural Meteorologist

*Department of Geography
Michigan State University*

The 2016 growing season will go into the books as warmer-than-normal statewide with highly variable precipitation totals and timing of the precipitation that fell.

It was preceded by an unusually mild fall and winter with strong El Nino conditions in progress across the equatorial Pacific region.

For the state as a whole, winter (December through February) temperatures averaged out at 27.8 degrees F, which is 7.6 degrees above normal and the fifth warmest winter on record since 1895.

However, thanks to an active and persistent storm track through the Midwest region (largely to the west and north of Michigan), seasonal precipitation totals were above normal, with a state average value of 7.39 inches (2.08 inches above normal).

Given the mild temperatures, a majority of the precipitation fell as rain, and seasonal snowfall totals in most sections of the state remained well below normal. Some of the 2015/2016 winter statistics are typical of El Nino conditions and others are not.

Temperature-wise, the preceding winter (December through February) was much milder than normal, which is very typical of El Nino events. However, El Nino winters more often than not are drier than normal, which is a reminder that not all El Nino (or La Niña) events are identical, and that impacts can vary significantly from event to event.

During April, an active northern branch of the jet stream led to the passage of a series of upper-air troughs through the Upper Midwest region, resulting in a cool and wet weather pattern across Michigan and extended fieldwork and planting delays.

April ended up cooler than normal statewide, with departures from normal ranging from 1 degree below normal across southwestern sections of the state to more than 5 degrees below normal across northeastern sections. Precipitation totals generally ranged from 1.5 inches to more than 3 inches (from less than 75 percent of normal to more than 150 percent of normal), a significant portion of which fell as snow in northern sections.

Snowfall for the month was heavier than normal in almost all areas of the state and exceeded 30 inches in most northern sections (more than 300 percent of normal in some areas). Given wetter-than-normal conditions for much of the preceding winter and at least portions of April, all but extreme southwestern sections of the state were categorized by the Palmer Drought Severity Index as 'Unusually', 'Very', or 'Extremely Moist' by month's end.

Persistent upper air troughing across the region through the first half of May resulted in a continuation of cooler-than-normal temperatures and prolonged fieldwork delays.

An unusually cold air mass moved across the state on the 14th-16th, bringing unseasonably cold temperatures and some (very) late season snowfall. Fortunately, the cold air mass was accompanied by mostly cloudy, windy conditions, which prevented surface temperatures from falling much below the freezing mark.

A major upper air pattern shift across the Upper Midwest took place during the third week of May with the formation of a broad ridging feature which would generally persist for much of June, July and early August.

The change resulted in a prolonged period of mild, dry weather that finally allowed rapid progress of spring fieldwork and planting. However, by the first week in June, the extended dryness resulted in abnormally dry topsoils, slow germination of late-planted crops, delayed activation of some herbicides, and initial moisture stress for some shallow-rooted crops. In southern sections of the state on well-drained soils, the dryness prompted initial use of irrigation several weeks ahead of normal.

Drier-than-normal weather continued across much of the state during June and July, increasing levels of moisture stress in many crops. As of the first week of July, precipitation deficits since May 1st (observed versus normal totals) increased to as high as 5 inches in parts of the state and the U.S. Drought Monitor categorized much of Lower Michigan except for the southwest corner in D0 "abnormally dry" or D1 "moderate drought" categories.

In contrast to areas with precipitation deficits, western parts of the state, including the western Upper Peninsula, recorded normal or even above-normal precipitation totals during the same time frame with near-ideal growing conditions.

For June, mean temperatures across Michigan ranged from 1 degree below normal across extreme northwestern sections of the state to almost 2 degrees above normal across southern sections of Lower Michigan. Precipitation totals for June ranged from less than 1 inch across south central sections of the state (less than 50 percent of normal) to more than 6 inches across western Upper Michigan (more than 150 percent of normal).

Continued warm and dry weather led to increasing levels of moisture stress during the first three weeks of July.

Daytime temperatures in the 90s and high levels of solar radiation increased potential evapotranspiration rates into the 0.25 – 0.28 inches of water per day range, which far exceeded the water available to the crops in most cases.

Later-planted crops were particularly impacted by the stressful conditions. Late in the month, a series of weak weather disturbances brought showers and thunderstorms to most sections of the state on the 21st, 24th, and 30th, easing persistent dryness in many areas and providing moisture just in time for the water-sensitive pollination stage for a significant portion of the state's corn crop.

Rainfall totals for the last 10 days of July generally ranged from 2 inches -4 inches across much of western Lower Michigan. In some areas it was the heaviest rainfall since early spring.

Unfortunately, rainfall totals across eastern sections of the state were much less, and dryness and moisture stress continued as a problem for many crops in that portion of the state.

For July, rainfall totals generally ranged from less than 1.5 inches (less than 50 percent of normal) across eastern and northern sections of the Lower Peninsula to more than 6 inches (more than 200 percent of normal) in western Lower and Upper Michigan.

TEMP = Mean temperature (°F)
PPT = Precipitation (inches)
GDD = Growing Degree Day calculated at base 50°F, with an 86°F cutoff
OBS = Totals observed in 2016
NORM = Normals calculated over 30 year period (1981-2010)
DEV = Deviation of observed from normal

Table courtesy of MSU Agricultural Weather Office (517-355-0231)

- Weather Continued From Page 4

Mean temperatures ranged from near-normal across western sections to more than 3 degrees above normal in the east.

One of the consistent patterns during the first half of the growing season was unusually high spatial variability of rainfall. For example, rainfall totals during July in Genesee County ranged from less than 1.5 inches in some sections to more than 8 inches in others.

As of early August, the driest areas of the state were found from south-central through southeast Lower Michigan, which represented a general eastward shift relative to earlier portions of the growing season.

A major jet stream pattern shift took place in mid-August, with the passage of a series of upper-air troughing features across the northern U.S. which led to an active weather pattern and heavy rain across portions of Michigan and the Great Lakes region during the second half of August into early September.

Heavy rain from the 13th-17th was associated with remnants of the weather system that had earlier caused devastating flooding across Louisiana and the Gulf Coast region.

Precipitation totals for August ranged from less than 2 inches across west central and northern sections of Lower Michigan to more than 10 inches across southwestern sections of the state, which improved late-season growing conditions for most crops. However, long-term dryness and some moisture stress persisted across northern sections of the Lower Peninsula.

Mean temperatures during August were above-normal statewide, ranging from about 2 degrees above normal across far western sections to more than 4 degrees above normal in eastern sections.

With warmer-than-normal conditions for much of the summer, seasonal growing degree day accumulations as of the end of August were generally 150-300 base 50 degree units above normal, which translates into 1-2 calendar weeks or more ahead of normal.

Warmer-than-normal weather continued for much of September and helped bring most spring-planted crops to maturity. A very slowly-moving upper air troughing system brought several consecutive days of moderate to heavy rain (1.5 inches to more than 3 inches) across portions of southern and central Lower Michigan from the 28th of September through the first of October, which brought most early harvest-related and fall fieldwork to an abrupt halt.

Mean temperatures for the month generally ranged from 2-4 degrees above normal. Precipitation totals for the month varied significantly across the state, ranging from less than 2 inches in east-central sections of the state to more than 5 inches in the north and west.

Given the late-season rains, the Palmer Drought Severity Index increased to 'Unusually Moist' across much of southern and east-central Lower Michigan and all of Upper Michigan, which is noteworthy as drought conditions had been a problem in some of those areas recently as mid-August.

As of the beginning of October, portions of northern Lower Michigan were still categorized by the U.S. Drought Monitor as 'Abnormally Dry'.

Upper-air ridging across the central U.S. brought a general continuation of warmer-than-normal weather to Michigan and the Great Lakes region during October into early November, which

favored crop maturation, grain drydown and fall fieldwork activities.

Mean temperatures for October generally ranged from 2-4 degrees above normal, resulting in the 7th consecutive warmer-than-normal month since March.

Not surprisingly, the first freezing temperatures of the fall season were much later than normal in many portions of the state. Despite the warmer-than-normal mean temperatures, a series of cool frontal passages brought periodic precipitation and cooler, more seasonable temperatures. One of these systems brought the first widespread snowfall to northern and central sections of the state on the 24th. The precipitation disrupted fall harvest and other fieldwork activities, and progress of corn and soybean harvest progress remained behind normal in most sections of the state.

For October, precipitation totals generally ranged from just under 3 inches in southeastern and northern sections of Lower Michigan to more than 5 inches across west central sections of the Lower Peninsula and central sections of the Upper Peninsula.

By early November, most of the state except for northern and western Lower Michigan was classified as, 'Unusually Moist' to 'Very Moist' by the long term Palmer Drought Severity Index.

- Season Continued From Page 3

Some fields were slightly more advanced than we like but, in the end, all fields were counted and thinned to a uniform stand. All locations except Grand Traverse County, MI and Wood County, OH were thinned back to a population of 35,244. Grand Traverse County was thinned to 31,284 and Wood County, OH was thinned to 34,452.

We began harvesting silage plots on September 9th in Wood County, Ohio and finished on October 7th with the Alger County silage plot. We are able to place 1,155 samples in the dryer at any given time; this space limitation accounts for some of the gaps in field harvest days. We were able to run approximately three days, depending on the size of the fields, before the dryer was full, leaving us with no other choice than to suspend harvesting until the samples could be removed. We also experienced a few delays with equipment adjustments.

Last year we saw significant improvements with our silage harvest equipment; this year we gained positive improvements for the grain harvesting equipment for the Michigan Corn Performance Trials. In August we took possession of a brand new Kincaid 8-XP combine. Grain harvest began October 30th on the Ingham County Conventional trial and ended on the Saginaw County plot on November 14th. We were fortunate to have only a single day when the rain shut us down. Grand Traverse County was dropped due to drought.

Table A (pg. 5) presents 2016 accumulations of temperature, rainfall, and heat units, plus their deviation from 30 year norms. Data is obtained from Michigan State University weather stations located closest to each plot location. Actual accumulation at each location may vary slightly. The weather summary is provided by Dr. Jeff Andresen from the Department of Geography using data from the Michigan State University Agricultural Weather Office.

2016 GRAIN PERFORMANCE TRIALS

Introduction

The grain index (pg. 26) contains a list of all hybrids planted in the 2016 grain trials.

County results are reported in the following tables:

Tables 1E/1L Zone 1 - Branch, Cass and Washtenaw

Tables 2E/2L Zone 2 – Allegan, Ingham and Saginaw

Tables 3E/3L Zone 3 - Huron, Mason and Montcalm

Table 4 Zone 4 –Grand Traverse, Iosco and Menominee, (Grand Traverse dropped due to drought)

Table 5 Zone 5 – Grand Traverse (E), Delta and Menominee (E)

Tables 6E/6L Conventional Trial – Ingham, Saginaw (Zone 2) and Montcalm (Zone 3)

The map of Michigan (lower right) shows each zone and the locations where the trials were located.

Methods

Three trial locations were planted in each of five maturity zones. These zones were based on available growing degree-day units established from long-term weather records. Hybrids entered in a zone were tested in each of the three designated locations. Entries for zone 1, zone 2, and zone 3 were divided into two maturity groups, early and late, on the basis of relative maturity (RM) provided by the seed companies. In zone 4 and zone 5, all hybrids were tested in one group.

Planting is accomplished with an Almaco vacuum planter. A cable with "bobbins" that are set at twenty-five foot intervals assure the uniform length of 22 foot long plots with a 3 foot alleyway and were planted at 30-inch row spacing. Four-row plots were used at all grain locations. The two center rows were harvested for yield. Experimental design, data acquisition, analysis of variance and data summarization were facilitated in part by AGROBASE Generation II™. The experimental layout was a four-replication, randomized complete block design. Hybrid performance is reported as the adjusted mean averaged together from four replicated plots.

Variety trials were conducted on farmers' fields and Michigan State University AgBio Research Stations. All hybrids in a location were managed uniformly with the same fertilizers, population, date of planting, and other management practices. In the field, hybrids were identified only by a plot number to assure unbiased comparisons. Trials in Branch, Cass and Mason counties were irrigated.

Stand counts were recorded in June. Plots with stand counts higher than the desired population were thinned at that time. Average trial population plus the desired population rates are listed with other important agronomic information in Table B (pg. 25). Lodging measurements were made during harvest. All plants broken below the ear and/or leaning more than 45 degrees were counted. Moisture content and field weights were measured by a Harvest Master™ single plot high capacity Grain Gage™ HM800 System that is mounted on the Kincaid 8-XP plot combine. Grain moisture is reported at the standard 15.5 percent.

Data was recorded on a Panasonic FZ-G1 Toughpad using Harvest Master™ Software. Grain test weight is reported at harvest moisture. Automated test weight equipment loses some accuracy as harvest moistures increase. Test weight values should be used to determine relative rank and not as a precise weight.

Results

The tables report the following information about the hybrids tested:

1. Moisture content at harvest (%H₂O)
2. Yield (in bushels per acre) of shelled corn corrected to 15.5 percent moisture (Bu/A)
3. Test weight at harvest moisture (Twt)
4. Percent of stalk lodging (plants broken below the ear and/or 45 degrees off vertical at harvest) (%SL)
5. Percent stand of target population (%Std)

2016 Grain Trial Locations

2016

SILAGE PERFORMANCE TRIALS

Introduction

The silage index (pg. 31) contains a list of all hybrids planted in the 2016 silage trials.

County results are reported in the following tables:

Tables 7E/7L Zone 1 - Branch, Lenawee, and Wood County, OH

Tables 8E/8L Zone 2/3 – Ottawa, Huron (Zone 3) and Ingham

Table 9 Zone 4 – Iosco, Menominee, and Osceola

Table 10 Zone 5 – Alger, Delta and Menominee (Early)

The map of Michigan (pg. 29) shows each zone and the locations where the trials were located.

Methods

Testing procedures (randomization, replication, planting rates, etc.) for silage evaluation are the same as those utilized for the grain trials. For silage Agronomic information refer to Table C (pg. 30).

Zones 1 and zone 2/3 were divided into two maturity groups designated early and late on the basis of the relative maturity (RM) submitted by the companies with results listed in separate tables. In cooperation with The Ohio State University, the Wood County, OH location is planted and managed by OSU while MSU handles harvest, quality and data analysis.

A New Holland T6.175 tractor powered a two-row Champion C1200 Kemper forage harvester and a rear mounted Haldrup M-63 Weigh system to harvest the two center rows. Electronic scales mounted on the Haldrup M-63 weigh system measured plot and subsample weights. All field data was recorded on a Panasonic FZ-G1 Toughpad using Harvest Master™ software. Total plot weight was used to calculate green tons per acre (**GT/A**). Sub samples of fodder including grain were collected, weighed, oven dried in a WRH586-500 Greives forced air dryer until weight loss was zero, then re-weighed to determine the percent dry matter (**%DM**). Dry tons per acre (**DT/A**) is calculated mathematically by multiplying **GT/A** by **%DM**. The samples were ground using a Cristy mill fitted with a 1mm screen before conducting quality analysis using Near-infrared spectroscopy (NIRS) to predict quality components.

Silage Analysis

Tables 7E, 7L, 8E, 8L, 9 and 10 provide silage quality data as determined by Near-infrared Spectroscopy (NIRS) analysis on freshly dried & ground samples. Data is provided for individual locations and also averaged over multiple locations. Near-infrared spectral analysis involves irradiating the sample with light in the near infrared spectrum (1,100 to 2,500 nm). The illuminated sample absorbs light proportional to specific chemical and physical properties. The reflected energy is measured and correlated statistically with the NIRS Consortium's calibration equation established for silage quality levels. Results of the six quality traits analyzed are presented in the quality tables. The six quality traits are:

1. **IVD= (in vitro) digestible dry matter-48hr.** IVD is a measure of forage digestibility. Higher IVD is desirable.
2. **ADF=acid detergent fiber.** ADF represents the less digestible portion of the corn forage, containing cellulose, lignin, and heat damaged protein. ADF is closely related to the digestibility of forages. Lower ADF implies the forage is more digestible. More mature plant material will contain higher ADF concentrations. A low concentration of ADF is desirable.
3. **NDF=neutral detergent fiber.** NDF is a measure of the fiber content of the corn forage. It is less digestible than non-fiber constituents of the forage. Forages with high NDF levels have lower energy. NDF is also a measure of potential forage intake. High NDF levels decrease the potential forage intake. Low NDF content is desirable.
4. **NDFD=neutral detergent fiber digestibility-48hr.** NDFD is the portion of neutral detergent fiber digested by animals at a specified level of feed intake. High NDFD is desirable.
5. **CP=crude protein.** Forages are generally supplemented with high protein concentrates such as soybean meal to increase the protein content of ruminant diets. Corn hybrids with high protein levels require less supplementation and therefore result in lower feed costs. High protein content is desirable.
6. **STRCH=starch.** Starch from the grain, along with the digestible component of the fiber, accounts for the majority of the energy in corn silage. High Starch content is desirable.

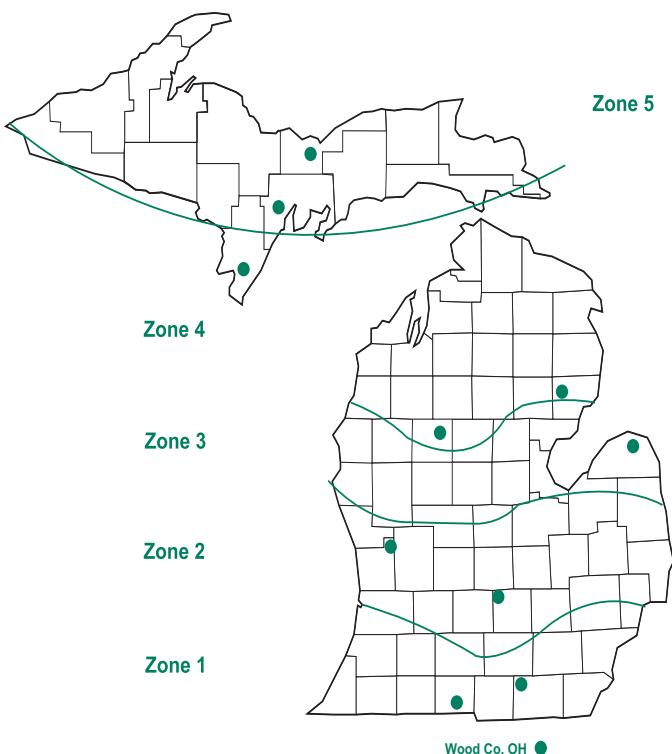

Silage quality traits are reported on a dry matter basis (100 percent DM). Quality traits in these tables are intended for use in hybrid selection only. Analysis for the balancing of feed rations should be analyzed from hybrids grown on each individual farm.

MILK2006

The MILK2006 equation (UW-Madison Dairy Science Department) was used to estimate MK/T (milk per ton) and MK/A (milk per acre). MILK2006 estimates the dry matter intake using the NDF and CWD (cell wall digestibility) parameters of the sample. The updated equation utilizes CP, fat, and sugar as well as the organic acid fractions along with their total-tract digestibility coefficients to estimate energy. Whole plant dry matter was calculated to 34% for all hybrids and digestibility coefficients used for the fat and sugars as well as the organic acid fractions were held constant. MILK2006 also assumes the weight of the cow is 1,350 lbs. and that it consumes a 30 percent NDF diet. Using National Research Council (NRC, 2001) energy requirements, the estimated intake of energy from corn silage is converted to milk per ton. Milk per acre is then calculated using the estimated values for milk per ton and dry matter yield per acre. For more information on the utility of MILK2006 please see:

www.uwex.edu/ces/crops/uwforage/Milk2006silage.html

FUNGICIDE EFFECTS ON MICHIGAN CORN PERFORMANCE

A.M. Byrne and M.I. Chilvers
Department of Plant, Soil, and Microbial Sciences
Michigan State University

Plots were established at the Michigan State University Agronomy Farm, East Lansing, MI. Corn variety 'P9807R' was planted on 19 May with 30 in row spacing and the experimental design was a randomized complete block. Plots were four rows wide and 22 ft long, with 3 ft alleys between plots. Fertilizer was added on two occasions: 12 Gal/A of 16% N at planting and 45 Gal/A of 45% N was side dressed on 12 Jun. Plots with stand counts higher than the desired population (34,848) were thinned on 1 Jul. Northern leaf blight (NLB) inoculum was applied to all plots on 15 Jun, by evenly spreading 92.5 lb of infested sorghum grain over the field. There were a total of 10 treatments and five replicates; fungicides were applied on 16 Jun (V5), 22 Jun (V6), 20 Jul (R1), 25 Jul (R1, timed for western bean cutworm control), and 4 Aug (R2). No irrigation was provided. Fungicides were applied with a hand-held spray boom pressurized with CO₂ at 40 psi. The boom consisted of six nozzles (Teejet 11001VS) spaced 20 in apart and was calibrated to apply 15 gal/A. Gray leaf spot (GLS) and NLB severities were determined by estimating the percent leaf area with lesions on the ear leaf and ear leaf +1 from 10 plants in the

center two rows (five from each row) for each plot on 12 Sep. A disease index (DIX) that accounted for both severity (DS) and incidence (DI) was calculated for each disease: DIX = DI*(DS/100). The center two rows of each plot were harvested on 21 Oct. Yields were adjusted to 15.5% moisture. Data were analyzed using SAS 9.3 PROC MIXED method (SAS Institute, Cary, NC).

NLB pressure was high, while GLS incidence was very low. All treatments, except the single application of Aproach Prima at R1 and the low rate of Stratego YLD at V6, resulted in significantly lower DIX scores for NLB on the ear leaf, compared to the non-treated. Results were similar for the ear leaf +1, except that none of the Stratego YLD treatments significantly reduced DIX values. For GLS, both the double application of Stratego YLD and the Zolera FX treatments significantly reduced DIX scores, compared to the non-treated. There were no significant differences noted for GLS on the ear leaf +1 ratings. Similar to previous years, despite some disease suppression, no products resulted in significantly higher yields, compared to the non-treated.

| Treatment, rate/A | Plant stage (date) | DIX ^z values | | | | Yield (bu/A) |
